Abstract: *This study investigates local expert perceptions of the role of environmental factors, especially in terms of contemporary climate change, in population movements from Bangladesh to India. The aim is to delve into locally held understandings of the phenomenon and to gain a better understanding of these migration processes, which are actively intertwined with local experiences. Both Indian and Bangladeshi experts were interviewed using semi-structured, in-depth interviews in order to explore insights from locally held perceptions and understandings of contextual factors. In total, 10 Bangladeshi and 15 Indian experts were interviewed, covering different disciplines, sectors, regions and job types, together providing a more complete and grounded picture of views of environmentally induced migration in Bangladesh and India. The results show that climate change is perceived by local experts as one of the key factors influencing migration in Bangladesh, both internally and externally. The interviewees, however, placed environmentally induced migration in a broader context of labour and economic migration. In particular, migration for environmental reasons in Bangladesh was evident long before the emergence of climate change as an issue. According to the interviewed experts, this does not preclude increased environmentally induced migration within and from Bangladesh in the future, but its analyses ought to be placed in historical and economical contexts.*

Keywords: *Bangladesh, climate change, India, migration, perception*

Introduction

Population movement around, to, and from South Asia is well documented, with environmental drivers impacting these movements (e.g. Hadi, 1999; Siddiqui, 2001; Khatri, 2007; Massey *et al.*, 2010). Climate change is now particularly prominent and extensively debated as an additional factor influencing migration around the world (e.g. Black *et al.*, 2011; Deshingkar, 2012; Bettini, 2013; Afifi *et al.*, 2015). The main challenge raised in the literature is that people typically move because of the combination of many environmental, economic and social factors, so decoupling climate change from the myriad of factors is not always easy or helpful.

Bangladesh is often depicted as one of the primary source countries of environmentally induced migration, while India is often

portrayed as being amongst the primary receiving countries of Bangladeshi migrants (Campbell *et al.*, 2007; CNA, 2007; GACGC, 2007). Such representations have been suggested as oversimplifying the complex connections between environmental change and migration. For instance, most evidence suggests that the majority of migrants affected by environmental change stay within their home countries and move temporarily, while groups which lack resources to move may be forced to stay behind in high-risk areas (Foresight, 2011; Felli and Castree, 2012; Kelman *et al.*, 2015).

This paper aims to shed more light on these discussions and narratives regarding environmentally induced migration from Bangladesh to India, in order to gain a more context-based picture. In order to do so, we engage with local experts' experiences and perspectives. The

importance is moving away from the domination of the topic by scholars, non-governmental organisations and think tanks from outside these countries and mainly from more affluent countries (Boas, 2014). The primary objectives of this paper are (i) to analyse experiences and perceptions of local experts regarding the role of environmental factors in population movements in Bangladesh and India, and (ii) to examine to what extent these viewpoints intersect or possibly conflict with findings from the international academic literature. A total of 25 local experts from India and Bangladesh were interviewed, selected from different disciplines, sectors, regions and job types.

Theory of environmentally induced migration

Although environmental change has been one significant driver of population movement throughout human history (e.g. Samers, 2010; Smith *et al.*, 2012), Piguete (2010) argues that the topic recently stayed on the periphery of the majority of migration studies. An important reason is that it is difficult to separate environmental factors from economic, political and other social reasons for moving (Perch-Nielsen *et al.*, 2008; Piguete, 2010; Stojanov, 2012). In the majority of cases, people do not move for a single reason. Additionally, not all environmental degradation or environmental change leads to significant population movement or even to the desire to move. Motivation to move involves a complex web of multiple factors that denote individual beliefs, interests and dreams along with collective decisions, within specific economic, social and political contexts (Stojanov *et al.*, 2014). Finally, there is no commonly accepted definition or methodology for estimating, calculating or classifying people moving for different levels of influence of environmental reasons.

Foresight (2011) and the response by Felli and Castree (2012) explore migration–environment connections due to various environmental change processes. Some geographers have responded to recent trends of environmental change influencing migration decisions by integrating them into migration typologies. For example, Stojanov *et al.* (2014) formulate a typology of environmentally induced population

movement on (i) environmental migrants; (ii) environmental displacees with two subcategories of slow-onset and rapid-onset environmental displacees; and (iii) development displacees. This typology provides a basis for considering a wide variety of motives for environmentally induced population movement, in relation to different drivers, motivations, time scales and space scales.

In recent years, the debate regarding environmentally induced population movement has been dominated by climate change impacts as a main driver. The predictions from IPCC (2013–2014) about future development might or might not come true in the future. In the meantime, a disconnect continues between those pushing the agenda of environmentally induced population movement on the basis of climate change only and those taking wider perspectives to understand root causes of people's movement while placing climate change in wider contexts (Stojanov *et al.*, 2014).

Summarising the literature, climate change and migration is a multi-faceted and dynamic process which is far from being completely understood (see also Upadhyay *et al.*, 2015). It is, as it always has been, a long-term process requiring knowledge from many disciplines and variability of methodological approaches in order to comprehend different options, lack of options, responses and non-responses from the affected population.

Migration in South Asia and environmental factors

For Bangladesh, internal and international migration is common for livelihood reasons and that has been the case for much of its history, including before independence (e.g. Hadi, 1999; Siddiqui, 2001; Van Schendel, 2005; Boas, 2015; Donato *et al.*, 2016). Cross-border immigration from Bangladesh (which was East Pakistan from 1947 to 1971) into India became an issue following India's partition in 1947. This region has always been characterised by a high degree of mobility (Van Schendel, 2005; Upadhyaya, 2006; McAdam and Saul, 2010), especially internal given that much of Bangladesh comprises a large and dynamic delta, with coastal subsidence and

river channels often morphing. As a result, inhabitants have constantly been moving in search of new land and livelihoods, with environmental change (but not climate change *per se*) amongst other factors being major influences.

The Indian discourse towards immigrants from Bangladesh was initially rather mild and welcoming, with many seeing them as children coming home, especially if they were Hindus moving after independence and partition (see also Weiner, 1978). This perception gradually changed over the decades. Immigrants, no longer moving directly as a result of the partition, were soon presented as being illegal infiltrators. The later groups of immigrants from Bangladesh were often Muslims and were seen as drastically changing the demographic composition of neighbouring areas in India such as Tripura and Assam (Van Schendel, 2005). Recent migration from Bangladesh to India is suggested as being the largest international flow between two sovereign countries because Bangladeshi communities have used migration as a tool to diversify and increase their income (ADB, 2012).

According to the Indian census from 2001, the total number of immigrants in India amounted to 5.1 million, of whom 59% were from Bangladesh and 97% were from all of India's neighbouring countries combined (Census of India, 2011). These are official data, which do not include unregistered migration. Most immigrants from Bangladesh to India end up in Assam and West Bengal and it is estimated that there could be as many as six million unregistered immigrants there from Bangladesh (Goswami, 2010; Nath *et al.*, 2012). Given that the total population of Assam province is 26 million, unregistered migration from Bangladesh represents a significant social, economic and political situation, often termed a 'problem' (Goswami, 2010; Kumar, 2010). Some Indian analysts even go so far as to suggest that sending migrants to Assam is an unofficial Bangladeshi policy for colonising Northeast India (Kumar, 2010). Anti-immigrant sentiment directed at Muslims in Assam is long-standing (Dass, 1980), sometimes turning violent such as in 1983 with thousands being massacred (Weiner, 1983). Singh (2009) reports the Muslim population at the beginning of the twenty-first century was 30.9% compared with 8–9% in 1950,

attributing separatist violence to be a reaction against these immigrants (see also Sinha, 2011).

This is not to argue, however, that all Indian analysts have such a negative view of unregistered Bangladeshi immigrants. There is a counter discourse presenting migration flows as a constant stream of labour supply benefiting India's development (McAdam and Saul, 2010), and there are concerns for the human rights of immigrants, both those deported and those locally affected (Dasgupta *et al.*, 2011). What makes the situation particularly harsh on the immigrants is that the governments of neither India nor Bangladesh recognise the unregistered immigrants. While India seeks to deport unregistered immigrants, the Bangladeshi government claims that the deported persons are Bengali-speaking Indians (Van Schendel, 2005). In the past, the deportees have often ended up in deportation camps along the Indian border, in jail in West Bengal or as migrants within India (Van Schendel, 2005).

Authors attribute different roles that environmental factors can play in migration processes, both within Bangladesh and from Bangladesh towards India. Ahmed (2008) suggests that the number of migrants from Bangladesh to India grows during disasters such as floods and droughts in Bangladesh (see also Saadi, 2003), and internal migration has also been shown to increase due to a disaster (Saha, 2016). Zaman (1991) notes that environmental reasons often lead to internal migration in Bangladesh rather than international migration; for example, nearly 88% of migrant households of Bangladeshi floodplain residents had moved not further than 3.2 km from their previous residence. Furthermore, population movement in the Bengal region (currently divided between India and Bangladesh) has always been intertwined with environmental factors, even prior to India's partition in 1947, as noted above. The advent of climate change has brought a new environmental factor into the influences on migrating.

The country is characterised by rapid urbanisation, high population growth, high population density and intensive land and resource use for agriculture and industry production, all contributing to Bangladesh's high vulnerability to environmental hazards, which are expected to become more evident under climate change (IPCC, 2013–2014; Khan, 2012; Mirza, 2003).

The main environmental changes induced by climate change in Bangladesh are expected to be sea-level rise, worse storm surges, more intense cyclones (although changes to cyclone frequency are uncertain) and changing precipitation patterns, all affecting floods and droughts, which in turn affect fresh water, food, homes and livelihoods (ADB, 2012; Ali, 1999; IPCC, 2013–2014; Khan, 2012; Kummu *et al.*, 2010; Mirza, 2003).

Karim and Mimura (2008) argue that, based on increasing flood depths and rising sea levels, Bangladesh is already being affected by climate change. Currently, almost 40 million people live in coastal Bangladesh. Loss of coastal land is predicted to reach up to 3% by the 2030s, 6% by the 2050s and 13% by 2080 (Pender, 2008), suggesting that millions of Bangladeshis will be at risk and may be forced to, or may choose to, move.

These physical changes are intertwined with other socio-economic problems faced by many Bangladeshis. Hutton and Haque (2004) point out that vulnerability in Bangladesh is associated with deeply entrenched socio-economic inequities. More than half of rural households have virtually no direct access to land, even though the majority depend on agriculture. Consequently, a vast proportion of the rural poor survive on subsistence livelihoods, with little opportunity to acquire savings or assets. Irrespective of the form or speed of environmental changes, millions of Bangladeshis have problems coping with daily life now, and they will have increased trouble in the future under climate change scenarios (see also Khan, 2012).

Despite the vast array of literature on Bangladesh regarding topics such as environmental change, vulnerability and migration, it is rare for studies to explore the experiences or perceptions of local experts, from Bangladesh and India, regarding links between these topics. The academic field on climate change, environment and migration is still largely dominated by scholars from Europe, Australia and North America, even though scientists affiliated with universities in Bangladesh and India are increasingly publishing on environmentally induced migration in Bangladesh (see e.g., Das, 2011; Gray and Mueller, 2012; Stojanov and Duží, 2012; Etzold *et al.*, 2014; Mallick and Vogt, 2014; Mallick and Etzold, 2015; Rahman *et al.*, 2015).

Yet examining local perceptions of environmental factors for migration in South Asia is needed for

identifying the discourses and representations of the relationship between environmental change and migration in the India–Bangladesh context. Such an assessment helps to combine local knowledge, witnessed experiences and existing findings from the literature, in order to gain a broader and deeper picture of migration and environmental change topics (Bardsley and Hugo, 2010; Weber, 2010).

Method

The data for this are qualitative, obtained from semi-structured, in-depth expert interviews (Mack and Woodson, 2005) of Indian and Bangladeshi experts on topics covering environmental change, development and migration (Table 1). Experts are from academia, the public sector, the private sector, governmental institutions and non-governmental organisations.

We first reviewed existing literature about migration and environmental change, especially from or related to Bangladesh, and searched for geographical and other information about the selected region. Using this material as a basis, we chose the field work locations of Dhaka and Khulna in Bangladesh along with Delhi, West Bengal (Calcutta) and Assam (surroundings of the capital Guwahati) in India. We selected experts in these locations on the basis of the literature, including their practical work in the field of migration, development and environmental issues. We aimed for a wide spectrum of representatives from academia, government, policy-making institutions and the non-profit sector to cover relevant fields and expertise and to gain diverse opinions and perceptions. The preliminary selected experts were contacted by email, and those who responded were invited to be interviewed. We started with the contacts who agreed to be interviewed followed by experts suggested by the interviewees and others, yielding snowball sampling, a method accepted within many qualitative methods (e.g. Babbie, 2008).

The main clusters of topics for the interviews were perception of migration in general, evaluation of recent migration patterns, selection of key environmental changes and their impacts, the role of migration in sending and receiving countries, evaluation of the recent environmental

situation, key environmental issues and future trends in region, and assessing whether and how experts link environmental issues with migration. Further questions on the social and environmental conditions of Bangladesh focused on manifestations of environmental change from climate variability, trends and change through to extreme weather, often identified as having perceived higher frequencies or intensities of environmental hazards. A common thread was environmental factors affecting livelihoods and living standards in the context of potential choices to migrate or to stay. Migration strategies in response to environmental changes, or

environmental changes as a trigger or impetus to stay or to leave, were also discussed.

In total, 25 respondents with various expertise, across numerous sectors and in a variety of positions, were interviewed, 10 in Bangladesh and 15 in India. Five of the respondents were female. Despite the imbalanced male–female ratio, it reflects the reality of the gender distribution amongst topic experts in both countries.

All the interviews were conducted in English, which was not a problem because the respondents are professionals, often with extensive international experience. The grammar from the respondents was not always correct, but minimal

editing has been done to the quotations, leaving some grammatical errors and stylistic inconsistencies. The interviews each lasted between 40 minutes and 3 hours. The respondents were guaranteed anonymity and confidentiality. The Bangladesh respondents are labelled with BAN and the Indian respondents with IND.

Results

Migration connected to recent and future environmental conditions

Most respondents expressed, in some form or another, concern about recent and future environmental conditions. They particularly highlighted climate variability and trends as having detrimental effects, including sea-level rise, floods, drought, cyclone intensity and rain variability. Numerous comments linked recent and future environmental and climate conditions to significant concerns for livelihoods.

Respondent BAN4 summed up what many others stated, in commenting on migration and climate change:

... three aspects: one is the frequency of the event, whatever that frequency will increase in future. The second is the intensity of an event, the hard damage of the extreme event ... Like usually the floods happen in July–August, reach September, ... the timing is going to be shifted. [This] third dimension is important in terms of its link with the production system. The flood decision timing is huge implications on an agricultural productivity. ... Now what is the projection. If there is one metre sea level rise, by end of the century, than this figure will become 25 million.

Respondent BAN7, in particular, used similar words, while respondent IND1 stated:

About future trends, the impact of climate change and rise of sea level in Bangladesh ... I expect increasing of migration flows ... This is alternative strategy for survival.

BAN2 supported this opinion:

Climate change will be a major impact on Bangladesh and it will have many difficulties for the people that live in the estuary area.

One will be physical inundation, flooding of that islands that they are here, so people have to physically move out. Second will be lost of livelihood because of the crops.

Respondent BAN6 views migration as one of the possible adaptation strategies for people living in climate change impacted areas in Bangladesh:

... some of them [families] might migrate, but there is a certain lost of crop, or there is this devour, lost of land to the river, or one member of household has accident, or dies. In that case others members feel how do cope with that. One important strategy is to send members abroad, so you know the shock is absorbed.

Respondents BAN4, BAN5, IND8, IND10 and IND12 had much to say regarding observations from local areas suggesting a definite shift in climatic conditions. They particularly highlighted seasonality, precipitation and increased flooding as being different from prior norms. They expected that similar changes in Bangladesh would increase migration.

Few patterns emerged in viewpoints based on geographic location, expertise, sector or location. Most respondents explained that recent environmental conditions have been different from the norm according to their experience. They expected future environmental conditions to continue to worsen and to have a detrimental impact on agriculture and other livelihoods, including on migration. This view was supported by respondent BAN4 who mentioned that due to the climate change, seasonal migration will increase as an environmental stress.

A number of respondents directly linked their observations of recent environmental conditions and expectations of future environmental conditions with contemporary climate change, namely indicating a strong contribution of human causation through global greenhouse gas emissions and land use changes (IPCC, 2013–2014). Their comments concentrated on sea-level rise as leading to migration, but other climate change factors highlighted were changes in river watercourses – especially bank river erosion and floods – and changes in monsoon and cyclone patterns. Many comments related to expectations of worse cyclones, storms and droughts due to climate change. These patterns

were linked to increased migration because, the respondents stated, Bangladeshi livelihood and economic patterns focus on farming (crops and livestock) and fishing, which depend on environmental conditions. If those livelihoods are harder to pursue, then people move.

Respondent BAN3 highlighted the view that sea-level rise could seriously affect '25 to 35 per cent of the Bangladesh population.' Respondent IND1 said that 'about future trends, the impact of climate change and rise of sea level in Bangladesh ... I expect increasing of migration flows; this is alternative strategy for survival'.

But not all respondents were so clear about cause and effect regarding climate change and their observations. Respondent BAN2 provided nuanced comments on climate change:

So this land is always changing, along the rivers ... new islands coming up and some islands are disappearing, so people also move from island to island. ... Even a few centimeters [sea-level] rise will cause many of the islands disappearing in the near future. On the other hand, new land is forming, people are cutting down trees in the Himalayas region, so we have more and more alluvial siltation. All the silt is deposited here and the new lands are coming up.

Respondent IND15 argued:

Migration is not yet related to climate change, but there are events where the weather is one factor. But to a large extent it is economic, as crops get ruined so they need to move as their agricultural land is under water and need to economically survive elsewhere.

In similar vein, respondent IND10 explained how flooding, erosion and related displacement, which have always been amongst the key features of the Ganges delta, are now being exacerbated by climate change. Respondent BAN6 also provided a more nuanced perspective of migration that:

Bangladesh is unique in the sense that many parts of the country has got river bank erosion...Many people lose out and they lose their land...They are forced [to move] some of them. Many stay behind. But some members, household members move on to find work in the city.

That is, climate change is impacting migration, but some people do not move irrespective of changing environmental conditions, while others move for non-climate reasons. Related to that, two Indian respondents (IND8 and IND15) highlighted that many people migrate only temporarily after an environmental hazard:

There are river bank erosions, floods. But it leads to displacement rather over a short period of time and they come back to the same place (IND15).

Environmentally induced migration in wider contexts

This study focused on perceptions of environmentally induced migration, so the responses reflected that topic. The respondents nonetheless placed environmental reasons for migrating into the context of wider migration discussions, particularly highlighting the long-standing economic and labour reasons for Bangladeshis migrating. Respondent IND3 directly noted that for Bangladeshi migration, 'the most important reason would be economic ... better livelihood conditions, access to land.' Respondent BAN9 pointed out the frequent situation when:

people do not say that they have directly come because of the river erosion or they have come because of flood. They say we have conquered better employment opportunity or in search for livelihood and etc. Upon further probing then I found what the immediate cause was, ... the erosion or flood. They lost everything

Respondent BAN6 focused on Bangladeshi migrants to India by noting that '... Indian economy is rising up, there is also need for this labor, in the construction sector ... the municipal corporations, they employ many people of Bangladeshi origin.' This view was supported by IND15 arguing that:

in Assam there is a labor deficit, why else would people move? There are not enough workers for infrastructure, as Indians do not want to come as it is slightly dangerous in Assam. ... cross-border migration has more to do with a lack of income than with the environment.

Respondent BAN4 connected environmental and labour migration:

there is a cyclone in the coastal area, people immediately move to the nearest urban town to seek the job, and then to the next larger town ... But this is a temporary and this is a seasonal trend of migration.

The implication is that environmental reasons might be a trigger or impetus for migrating – a definite push factor – but the pull factor remains better jobs. Oscillating between two or more places is also a common strategy for Bangladeshis. Respondent BAN4 added that ‘now they are also permanent immigrants as a last resort or a last option for community or the household when they completely lose their homestead and their livelihood system in that locality’. Respondent BAN5 referred to migrants in saying ‘those are rich because they have the capacity to buy land and build the house. The poorer, they go through a process [move from the place of origin].’ That is, for some of the population, migration is not desired, but is nonetheless accepted when necessary.

Wider contexts than climate change were provided by Respondent BAN1 who argued that environmental conditions are the second-most important reason for Bangladeshis migrating to find employment:

it is true that it [floods] is thousands years old issue ... and people’s movement was there too, that is one point and other things that population density increased incredibly, that is another problem, so river erosion now affects more severely, than it affected earlier.

Similar comments were made for agriculture, seeing migration as a common response strategy when crops fail.

Respondents also described the historical nature of population flows between Bangladesh (in the past, East Pakistan and East Bengal) and India, particularly migration to West Bengal and Assam (see also Prakash, 2007; Panda, 2015). The ‘international’ nature of this migration is relatively recent: post-1947 when India and Pakistan achieved independence. Respondent IND2 even proclaimed that each person who crosses the Indian border could be viewed as an Indian citizen because there is no effective

control of citizenship based on documentation. To a large degree, migration of Bangladeshis is accepted as the usual state of affairs. That covers both temporary and seasonal migration, usually to Assam from border areas of Bangladesh, as well as permanent migration from all over Bangladesh to areas in India with jobs or where friends and relatives already reside. Respondent IND3 stated that:

boundaries are open, you can smuggle contraband ... and come across the border in four hours, even less ... you can come across in one hour or so, in the small boat ... and that is happening ... They can cross in many parts of the border ... It is obvious that India has put the border with Pakistan at higher priority than with Bangladesh. We are still in the process constructing border fencing almost 23 years after 1985.

Some of the Indian respondents (IND1, IND3, IND11) along with BAN2 believed that migration flows from Bangladesh to India have actually declined over the last three decades or so because of increasing opportunities in Bangladesh. Bangladeshi migrants have also started to move to other countries. For instance, large populations of migrant Bangladeshis now work in the Middle East due to fewer jobs and less free land in Assam, as well as stricter border protection. In this context, Respondent BAN6 described the gradual out-migration process:

... workers from rural areas, they came to the urban areas to work in manufacturing sector ... they feel empowered, they have information, there is job in Malaysia, there is job in Kuwait, ... So rural to urban migrants now aspire to be international migrants, because they have got information.

That did not stop some respondents from India (IND1, IND2, IND3, IND6 and IND7) expressing fear about the ethnic and environmental future of Assam due to the Bangladeshi immigrants. They stressed the relatively high birth rate of Bangladesh immigrants in comparison to Indians in Assam – with IND3 suggesting that Assam’s population is ‘26.6 million from 2001 census. My estimate is around 30 million, may be 30 plus’ – while claiming that grazing and forest land are being taken over for farming

by the immigrants. Respondent IND1 stated that for Assam, 'now the population is very high. So the sources are available there, but water resources, land resources are no longer sufficient to support lots of people getting there. It crosses the capacity of the land therefore, they want to migrate within Assam, from one area to other area to migrate.' Respondents IND1, IND3, IND6 and IND7 suggested that the Bangladeshi immigrants amount, at minimum, to one-third of Assam's population and that deforestation by the immigrants presents one of the biggest environmental problems. IND2 was direct in asserting that the immigrant flows are 'a sort of demographic aggression' against the native Assam population.

There were also a number of Indian respondents who were critical of this negative sentiment towards Bangladeshi immigrants. IND15 for instance referred to the role of the media in fuelling these negative perceptions: 'In the media in Assam there is always talk of this fear of the other, it is pushed by emotions'. IND11 also referred to the situation in Assam as a case of 'xenophobia against immigrants'. Along similar lines, an opinion article in the newspaper *Tehelka* maintains that attention should be given to underlying problems, such as a lack of both available land and job opportunities, instead of simply blaming the Bangladeshi immigrants (Puniyani, 2012; Panda, 2015).

Finally, it is interesting to note that interviewed migration officials in the central government of India were reluctant to connect climate change or other environmental factors to cross-border migration from Bangladesh. Instead, they argued that these population flows were mainly economically driven (IND13, IND14). In contrast, governmental respondents outside the central government did discuss climate change as an increasing factor leading to cross-border migration. For example, Respondent IND8 from the Government of West Bengal noted that 'unfortunately, the Sundarbans in Bangladesh is even much poorer than the Indian part. And the border is porous. So large scale migration across border in response to climate change can not be ruled out'. This finding suggests that political contexts matter in framing and perceptions of environmentally induced migration. Linking cross-border migration to climate change is a more sensitive endeavour for

the central government responsible for India's climate policy and the climate change negotiations (Boas, 2015).

Furthermore, local experts from West Bengal may be more concerned as they are close to the Bangladeshi border and come from a region more directly affected by environmental impacts at the moment. As noted by respondent IND8:

Probably the Central Government has not yet identified climate change induced migration as a big threat because it is not going to take effect until the latter part of the century, that is the common perception. People in West Bengal are more worried because of the Sundarbans. We are watching one cyclone after another hitting the Sundarbans and their intensity is increasing day by day ...

Discussion

Respondents from both countries confirmed that there are several interacting reasons for migration within and from Bangladesh, while indicating that economic reasons tend to play the most significant role in decision-making regarding migration, in both pull and push factors. They noted how the combination of many other factors – historical, economic, demographic, social (e.g. health, education, family and friends) and environmental – influence the decision to migrate or not to migrate. If the decision is to migrate, then further choices need to be made about the destination, the timeframe, who goes and whether the migration is intended to be temporary or permanent. These complexities are well established in the migration literature (e.g. Massey *et al.*, 1998; Castles and Miller, 2009; Samers, 2010) as well as for Bangladesh specifically (e.g. Hadi, 1999; Siddiqui, 2001; Khatri, 2007), triangulating the experts' views on this particular question as being realistic, sensible and grounded.

Based on the experience from Bangladesh and India reported here, the results also corroborate a principal reason for why environmental change has been on the periphery of migration literature: that there are so many other factors influencing migration (Hugo, 2008; Perch-Nielsen *et al.*, 2008; Piguete, 2010; Stojanov, 2012). Nonetheless, most of the respondents placed recent environmental disasters and

extreme weather events within the wider context of climate and environmental change, connecting local experiences with climate change. Whether or not specific events or trends are indeed linked to climate change is an open question, but the experts certainly perceive that to be the case and the literature suggests that it will be increasingly likely in the future, especially for Bangladesh. Consequently, environmental reasons for migration are not to be diminished, suggesting that migration studies could engage more with environmental factors within their theoretical concepts, especially for determining the degree to which specific environmental factors do or do not play roles in migration-related decision-making.

The experts' experiences and perceptions provided three specific ways forward. First, a focus on the role of environmental change in economic- or labour-related migration decision-making. Experiences such as floods, droughts and water/land salination might undermine livelihoods, informing the impetus to move as part of deeper desires to seek better livelihood opportunities. Second, instances were raised where the main or sole reason for migrating was an inability to cope with environmental changes, whether rapid such as cyclones or longer term such as changed seasonality or precipitation patterns. Again, the expert views on these matters were fully in line with the literature, which extensively covers forced migration due to weather-related environmental hazards such as cyclones (e.g. Paul *et al.*, 2010), other environmental hazards such as volcanic eruptions (Tobin and Whiteford, 2006) and longer-term creeping changes such as land use (Glantz, 1999). Third, the experts' perception was that environmental impacts on internal and cross-border migration were gradually being exacerbated due to climate change's effects.

It was nonetheless highlighted that such climate change-related migration takes place within wider migration contexts and cannot be seen as separate from other social-economic forces. In fact, all three points converged to the baseline that environmental changes are one factor amongst many influencing migration. Even for the second point above, in which inability to cope with environmental changes was the main or sole reason for migrating, this inability to cope needs to be seen within wider

social and economic contexts. For instance, resource allocation, inequity and prejudice can interfere with coping ability. The experts' experiences and perceptions for this baseline match that of the literature.

By presenting a balanced discussion, the experts also provide a more nuanced view that challenges the rhetoric about hordes of 'climate change refugees' ready to flee climate catastrophe, a viewpoint which has been critiqued and shown to lack an empirical basis (Hartmann, 2010; Bettini, 2013; Baldwin, 2014). Instead, migration due mainly to environmental changes, such as climate change impacts are neither sidelined nor dominating.

As with studies factoring climate change into wider views of migration, the experts here looked beyond a direct cause-effect connection, instead describing a more complex series of linkages. In particular, sea-level rise connects to greater intensity and frequency of inundation along with erosion, which, through a complex interplay with livelihoods and poverty, can lead to migration for those who can afford to do so. This view matches well with literature describing migration and return decisions in the context of livelihoods (e.g. Tobin and Whiteford, 2006 and, for Bangladesh, Penning-Rowsell *et al.*, 2013), suggesting that if the ability to cope with the environmental change existed, then many would not consider migration as an option. The decision process works in tandem with migration being an ever-present option for those seeking better livelihoods or simply opportunities to send remittances back to their families (e.g. Hadi, 1999 and Barai, 2012 for Bangladesh).

In fact, short-term migration, permanent labour migration and circular migration are all standard coping strategies under multiple scenarios and for improving quality of life. Environmental factors are not precluded as one set amongst many influencing migration decisions, nor does the situation preclude environmental factors as dominating migration decisions in some circumstances. In fact, the majority of the experts' perceptions concur with these manifold views of migration, including those in the context of climate change. For Bangladeshis, despite the severe implications of climate change, which could provide additional migration pressures, mobility has always been part of their livelihood strategies in Bangladesh and India.

This nuanced approach by the experts reflects the literature expressing the challenge of attributing specific causes to specific migration decisions or trends (e.g. Massey *et al.*, 1998; Bardsley and Hugo, 2010; Crawford and Campbell, 2012). If weather or seasonal conditions change crop yields or affect livestock, it could be due to climate variability, climate trends, climate change, economic variability, economic trends, economic changes or a combination. Irrespective, the people affected must make a livelihood decision: should they remain, should some of the family leave (and for how long) or should all of the family depart (and for how long)? There might also be geographic disparities, such as the decision being more attributable to economic than environmental factors in north Bangladesh, away from the sea, whereas sea-level rise could be the main driver of migration in the southern coastal parts.

Caution is needed not to be too assumptive about choices made by Bangladeshi immigrants, considering the complexities of how Bangladeshis adjust to environmental hazards including storm surges and riverbank erosion (e.g. Zaman, 1994; Paul, 2009; Paul *et al.*, 2010; Penning-Rowsell *et al.*, 2013; Shaw *et al.*, 2013). Additionally, the concerns displayed by some of the respondents – in terms of blaming the Bangladeshi immigrants for local problems in India and being worried about being taken over by immigrants – were in stark contrast to the more neutral views expressed in other parts of the interviews. The fears of undue 'foreign' influence among some cohorts of Assam's population have a long historical pedigree predating the more recent environmental degradation in this area. The antagonism of some of Assam's population to Bengali 'foreigners' can be traced back to the British colonial rule.

Moreover, anti-immigrant sentiments have characterised some of Assam's political movements throughout the decades, including violent insurgent groups such as United Liberation Front of Assam. On the other hand, even though the liberation struggle of Assam was united with the Indian freedom struggle during British colonial rule, many Assamese hoped for their own independent state. Because independence has not materialised, several groups such as United Liberation Front of Assam have been waging a

low intensity war against the Indian government and using anti-immigrant sentiments to gain support.

As such, two further contexts need to be considered, to which the experts alluded. First, the dominating trend of rural-to-urban migration flows in Bangladesh (Hadi, 1999; Goswami, 2010). It seems that the Bangladeshi migrants are often more concerned about reaching urban areas with the expectation of jobs there, rather than about which particular country they end up in. Second, the economic characteristics of Bangladeshi immigrants who, in India, generally come from the middle class and middle-upper class, whereas internal immigrants also include low-income categories. The difference is related to affordability: people with higher socio-economic status use their resources to leave Bangladesh. Those with lower resources tend to stay in Bangladesh, though they might migrate internally. Within these migration patterns, many of the more affluent migrants acquired their financial resources through migration, either themselves or a family member working temporarily in, for example, the Middle East. While climate change and other environmental reasons are expected to continue to influence migration according to the experts, any migration in Bangladesh is expected to continue to conform to these established patterns.

Conclusions

This study investigated experiences and perceptions of local experts from India and Bangladesh regarding environmentally induced migration within and from Bangladesh, especially in the context of contemporary climate change. The experts identified environmental factors as influencing migration in Bangladesh and expressed fears that climate change would have a significant influence on future migration. But they placed these factors into wider contexts, notably highlighting labour and economic reasons for migrating while describing the long-standing history of migration within Bangladesh for environmental and non-environmental reasons.

The experts' experiences and perceptions match well with the migration literature indicating that the environment, including climate change, can be a migration driver, but that the

level of influence differs depending on the specific case study and timing (e.g. Hadi, 1999; Siddiqui, 2001; Khatri, 2007; Massey *et al.*, 2010; Black *et al.*, 2011; Warner, 2011; Deshingkar, 2012). The majority of the experts' views also match well with the critiquing literature on massive flows of 'climate change refugees' indicating subtleties and nuances regarding the understanding of migration movements (Gibb and Ford, 2012; Hartmann, 2010; Bettini, 2013; Baldwin, 2014; Baldwin *et al.*, 2014). These are important contributions because much is written about environmental change, vulnerability and migration for South Asia, especially with respect to Bangladesh and sea-level rise, but such contributions, especially the most well-known ones, predominantly come from scholars from outside these countries and mainly from more affluent countries. It is rare to find research which examines the experiences and perceptions of local experts regarding links amongst these topics. This paper further adds to the literature by including perceptions and experiences from experts who are not trained as scientists, but who are journalists or who work in the public or private sector.

The experts' views and the analysis indicate some lines of future research. First, studies of experts' perceptions and of migrants' perceptions could be combined by bringing them together in focus groups to discuss reasons for and views of migration. Such research would help to triangulate the data from each group separately yielding further insights into how local experiences and decisions fit into wider trends and patterns, while giving the groups the opportunity to compare and contrast their experiences with each other. Second, with some prejudices emerging from some of the expert respondents, it would be useful to explore those further to determine how much those prejudices do or do not influence their other remarks. For example, is it possible that environmental factors forcing migration are downplayed due to anti-immigrant hostility in order to try to blame the migrants for moving? How much might the international literature reflect or counter any such bias?

Third, it is important to highlight local views on environmentally related migration and non-migration processes to counter an affluent country bias in the literature on climate change and

migration. Alarmist discourses about climate-related mass migration and resulting insecurity, conflict and chaos in areas such as India and Bangladesh often find their origin in the more affluent countries (Boas, 2014). Without immediately suggesting that groups are necessarily right or wrong, the comparison, contrast and balance are important to the production a fuller, more robust picture. Fourth, what are the policy implications for addressing migration induced by, linked to or influenced by climate change when such migration occurs within much wider migration contexts? Could discouraging environmentally induced migration, or supporting these immigrants to settle as near their original home as feasible, end up inhibiting remittances and other livelihood-related migration, which have long been a necessary part of Bangladeshi livelihoods (e.g. Sikder and Ballis, 2013; Hatemi-J and Uddin, 2014)?

Migration is, and always has been, a complex process affected by multiple factors (Massey *et al.*, 1998; Castles and Miller, 2009; Bardsley and Hugo, 2010; Samers, 2010). With environmental conditions changing rapidly, and with the expectation that Bangladesh will be significantly affected by climate change, different scenarios of environmentally induced migration ought to be explored. As the local experts indicate, environmentally induced migration should not be assumed to be inevitable or dominating, a position which matches the wider literature.

Acknowledgements

The authors are thankful for the support from anonymous respondents and for their willingness to share their opinion on researched topics. The presented paper was partly supported by the project for the long-term conceptual development of research organization, RVO 68145535. The author Barbora Duží is very thankful for the support.
